## FOREWORD

The functionalization of projectile ballistics data described herein was conducted by the Naval Weapons Laboratory during Fiscal Years 1971 and 1972. This work was sponsored jointly by Independent Exploratory Development Funds and by the Naval Ordnance Systems Command.

This report was reviewed by R. D. Cuddy, Head, Aeroballistics Division.

Released by:

RALPH A. NIEMANN

Head, Warfare Analysis Department

## ABSTRACT

The Effective Drag Functions derived by the Naval Weapons Laboratory for the computation of gun ballistic data in digital gunfire control systems are presented. The accuracy and derivation of the functions are given as well as the least-squares coefficients computed for 3- and 5-inch projectiles. FORTRAN listings of the three programs used in the computation of the coefficients are given in the appendices.

## I. INTRODUCTION

Reference 1 states: "A gun weapon system is functionally composed of the following elements: (1) a fire control system, (2) one or more gun mounts organized as a battery, and (3) ammunition supply arrangements. With guns, fire control can be considered as the practical application of exterior ballistics to ensure that the projectile will hit the target. In any weapon system, the fire control problem is essentially that of getting the weapon or projectile to hit the target and explode, or at least to explode when the target and the weapon or projectile approach close enough for maximum damaging effect. In gun weapon systems, the problem is to *lay* (aim) the gun in such a way that the projectile will hit or approach close to the target. Unlike other types of weapon systems, once the projectile has left the gun muzzle, nothing further can be done to affect its course. The gun's fire control problem ideally must be solved before the gun fires. To solve the gun fire control problem, it is necessary to deal with three main types of variables: (1) exterior ballistics, (2) target position and relative motion of target and own ship, and (3) inherent corrections necessitated by the physical characteristics of the weapon system and the medium on which its carrier floats."

As indicated above, one of the major roles of the fire control system is to accurately predict the exterior ballistic performance of the projectile since nothing can be done to affect its course once it has exited the muzzle. Ultimately then, the accuracy with which the system can predict the projectile's trajectory provides an upper limit on the capability of the system to achieve its designed purpose, i.e., incur maximum damaging effect on the target. From the instant the projectile leaves the muzzle of the gun until it ends its flight by impact or explosion, the projectile trajectory is affected by the following factors: (1) momentum, (2) gravity, (3) air resistance, (4) wind, (5) drift, (6) earth's rotation (Coriolis), and (7) earth's curvature. Thus, the fire control system must make provision for these factors in aiming the gun such that the projectile will intersect the path of the target.

Normally, a range table<sup>1</sup> (i.e., firing table) is constructed for each projectile based on exterior ballistics theory and information gained from the analysis of instrumented flight tests of the projectile. The range table is based on a set of nominal or standard firing conditions for the weapon and provides differential effects for variables such as initial velocity, projectile weight, air density, air temperature, wind, and gun and target motion. The table gives elevation angle, time-of-flight, and drift for standard firing conditions; using the differential effects, corrections can be applied to the data for standard firing conditions to obtain a gun elevation angle

---

<sup>1</sup>See Reference 2, 3, and 4.

and an azimuth angle for any combination of firing conditions that may exist. It should be noted that the range table is an approximation to the trajectory of the projectile. Solutions for non-standard firing conditions have inherent errors in them due to the non-linearity of the differential effects given in the table and the interaction of multiple effects operating simultaneously.<sup>2</sup>

Reference 1 defines *fire control computers* or *rangekeepers* as electronic or electromechanical devices into which are fed the mathematical variables in the fire control problem, and which yield solutions in the form of control settings (e.g., gun orders) required for the weapon and launcher to have maximum effect on the target.

All operational gunfire control computers in the U. S. Navy are analog and use either mechanical cams and/or potentiometers and other electronic circuitry to essentially reproduce the minimally essential columns of the gun range table.<sup>3</sup> The later versions are electrical analog using modern solid state circuitry to approximate relatively simple polynomial functions which regenerate portions of the range table. The functions are necessarily simple and either neglect some of the variables which affect projectile flight or only correct for their variations in an approximate fashion. These simplifications are required on the basis of economy and space limitations. For example, none of the analog systems provide inherent corrections for Coriolis or consider the effects due to the interactions of several variations from standard firing conditions occurring at once. It should be noted that under certain conditions provision is made to correct for factors which have smaller influence on the flight of the projectile than those that are neglected. Interaction effects under certain conditions can influence the flight of the 5-inch MARK 41 projectile as much as 5 mils, a value generally considered larger than the dispersion of the round itself.

By the early 1960's, computer technology had advanced to the state that digital computers were being built that could be used to solve the tactical fire control problem. The substitution of digital for analog computers showed promise of much greater flexibility and sophistication and therefore greater accuracy in the solution of the gunfire control problem. For example, in the area of exterior ballistics it permits a much more accurate prediction of the trajectory of the projectile than was possible with the analog computer. Ideally, the best approach to predicting the trajectory of the weapon in the fire control system is to numerically integrate the differential equations of motion within the fire control computer. However, this is an iterative time-consuming process which has not yet been proven practical in the gunfire control computer, especially in light of the high frequency

---

<sup>2</sup>See Reference 5.

<sup>3</sup>See Reference 6.

of solutions needed to achieve system stability. The most feasible alternative is to develop ballistic functions to approximate the trajectory data obtained from numerical integration of the equations of motion. With the digital computer, this can be done with a degree of accuracy which is practically impossible with the analog computer.

Since its inception, the Naval Weapons Laboratory (NWL) has been the Navy's prime facility for exterior ballistics for surface-launched unguided weapons, including guns. In the early 1960's, NWL was asked by the Naval Ordnance Systems Command (NOSC) to serve as technical advisor to Lockheed Electronics Company (LEC) in the development of the U. S. Navy's first digital gunfire control system. Range tables and specialized ballistic data were provided to Lockheed in support of their efforts which included implementing the range tables in the system. The ballistic functions used in the MARK 86 GFCS are partitioned cubic least-squares polynomials fit to the essential columns of both the surface and anti-aircraft range tables for 5"/54 caliber gun. The ballistic solution is essentially one of applying differential corrections to range and time of flight to obtain gun orders such that the projectile will strike the target under any reasonable non-standard firing conditions that may exist. The solution is analogous to that described in the introductory information to the surface range table.

Initially, the MARK 86 GFCS was designed as a surface only system; therefore, no provision was made to include ballistic solutions for anti-aircraft (AA) targets, that is, targets at non-zero position angles. When the decision was made to add an AA capability, surface-type range tables were fit with polynomials (identical to the procedure for the surface table) for various position angles. To obtain an AA solution with the system, surface-type solutions are obtained for three position angles which bracket the target position angle; quadratic interpolation is then performed among the three surface-type solutions for the position angle of the target.

This procedure requires a large amount of computer storage since it is necessary to store coefficients of the least-squares fits for position angles from zero to 65 degrees in increments of five or ten degrees. Since these functions essentially reproduce the columns in the range table, they contain the deficiencies inherent in the range table; they do not compensate for interaction among the independent variables used in the computation of gun and fuzing orders. Also, in the surface mode, a non-zero target height is compensated for by rotating the surface solution through the position angle. This is acceptable for small position angles, up to approximately six degrees, but introduces fairly large errors at higher position angles.

In 1969, the NWL initiated a modest in-house research program to further investigate techniques for the implementation of gun ballistics in digital gunfire control computers. The program was motivated by the anticipated need for implementing gun ballistics for long-range and guided projectiles, a desire to overcome the shortcomings inherent in the techniques used in the MARK 86 GFCS, and the experience gained in investigating similar problems associated with airborne digital fire control systems.

Rather than attempt to fit the columns of the range table as was done in other approaches and thus retain the deficiencies inherent in the range table, the NWL approach was to first determine a closed-form approximate solution for the basic equations of motion used to mathematically simulate the flight of the projectile and produce the range table. This approach uses an "Effective Drag" which is determined for each data point as a function of slant range, position angle, initial velocity, ballistic density and temperature by substituting into a 20-term expression the values of each of these variables. This Effective Drag is then substituted into the closed-form expression for elevation angle. Time-of-flight is computed similarly using elevation angle and the variables mentioned above.

After deriving the Effective Drag Functions and comparing the accuracy and storage with the functions used in the MARK 86 system, the Naval Ordnance Systems Command (NOSC) funded NWL to tailor the functions to 5"/54 caliber and 3"/50 caliber ammunition for use in the digital version of the MARK 68 GFCS, the most widely used naval gunfire control system. In addition, after discussions with NOSC and LEC personnel, NWL and LEC were funded to investigate the feasibility of replacing the ballistic functions in the MARK 86 system with the Effective Drag Functions. This feasibility study concluded that the effective drag functions should be used in the MARK 86 system in place of the LEC functions. Further information concerning the feasibility study as well as other significant conclusions of the study can be found in Reference 7.

## II. TRAJECTORY DATA

The trajectory data used as reference data in the computation of approximating functions were computed using a two-dimensional particle integration program (see Reference 8 for an example of this type of program). The model employs a fourth-order Runge-Kutta scheme to numerically integrate the equations of motion subject to the following assumptions:

1. The earth is flat and non-rotating with gravity varying as a function of altitude.
2. The projectile is a point mass.
3. Drag is the only aerodynamic influence.
4. The atmosphere is Navy Standard (NAST).

The initial conditions (initial velocity, elevation angle), atmospheric conditions (ballistic density, ballistic wind, ballistic temperature), and terminal conditions (flight time for AA mode, target altitude for surface mode) were selected based on the conditions encountered in the tactical use of the MARK 68 and MARK 86 systems. Table 1 lists the type of distribution assumed for each variable as well as the range of conditions used for the functionalization.

TABLE 1

## RANGE OF CONDITIONS FOR FUNCTIONALIZATION

Variable	Type of Distribution	Minimum/Maximum	Mean	Standard Deviation
Elevation Angle	Uniform	0°/70°		
Initial Velocity	Uniform	1300 fps/1600 fps (reduced charge 5"/54) 2300 fps/2700 fps (full charge 5"/54) 2450 fps/2750 fps (3"/50)		
Ballistic Density	Normal		100%	3.5%
Ballistic Temperature	Normal		59°F	25°F
Ballistic Range Wind	Normal		0 kts	20 kts
Time-of-Flight (AA only)	Uniform	0/30 sec		
Target Altitude (Surface only)	Uniform	-50/5000 ft		

### III. TRAJ COMPUTER MODEL

To generate the trajectory data reflecting the distributions for each variable, a computer model "TRAJ" was developed by NWL personnel. The program is a variation of the basic particle trajectory integration program discussed in Reference 8. The only significant difference between the models is the method used to select initial, atmospheric, and terminal conditions for each trajectory. The basic particle trajectory model requires input values for each of the independent variables whereas the TRAJ programs selects the values for each of these variables based on random sampling from the distributions assumed for each variable. To accomplish the random sampling, the parameters for each of the distributions are input to the model along with the total number of trajectories to be integrated. After integrating these trajectories, the model arranges the trajectory data in ascending order of slant range (surface) or time-of-flight (AA) and prints out the results of the integration along with the initial and atmospheric conditions used to generate the trajectories. In addition to the usual trajectory variables computed by the model (slant range, position angle, time-of-flight, and drift), the effective drag value and the ratio of the tangent of the orientation angle at termination to the tangent of the superelevation angle are printed out. The effective drag value is computed using the following equations:<sup>4</sup>

$$XVAC = \frac{(UM)^2 \sin(2Eg^*)}{(G)(\cos E4^*)}$$

$$N = \frac{XVAC}{Rh4^*}$$

$$FK = \frac{-1 + \sqrt{3N - 2}}{R4^*}$$

If a non-zero value of range wind is generated by the random sampling technique, the model computes all of the above data with respect to the moving air mass. For further explanation of these calculations, see the listing of the TRAJ model given in the appendices. If the target height used to terminate the trajectory is greater than the maximum ordinate of the trajectory, the generated trajectory is discarded and a new set of conditions is generated using the random sampling technique.

---

<sup>4</sup>A glossary of terms is given in the appendices.

#### IV. BALLISTIC FUNCTIONS

The ballistic functions were derived from the differential equations of motion for a point mass. Since these equations have no closed-form solutions for non-vacuum trajectories in terms of elementary functions only, the solution is obtained by approximating the true solution. The functions obtained by this approximation are as follows (The derivation of the superelevation angle function is given in the appendices and the derivation of the time-of-flight function is given in Reference 10.):

$$V4^* = \frac{1}{2} \sin^{-1} \left[ \frac{G \cdot N \cdot Rh4^*}{UM^2} \right]$$

$$T4 = \text{SQRT} \left[ \frac{6 \cdot A \cdot UM \cdot \sin Eg^* - 6 \cdot RV - G \cdot A^2}{2 \cdot G} \right]$$

where

$$N = 1 + (K \cdot RS)(2 + K \cdot RS)/3$$

$$A = \frac{Rh4^*}{UM \cdot \cos Eg^*}$$

To overcome the poor accuracy of the superelevation equation, for long times-of-flight, the quantity "K" is replaced by the term "FK" which is expressed as a least-squares function of initial, atmospheric, and terminal conditions.

AA mode

$$\begin{aligned} FK = & K1 + K2 \cdot US + K3 \cdot RS \cdot US \cdot DS + K4 \cdot E4S + K5 \cdot DS + K6 \cdot US \cdot DS \\ & + K7 \cdot RS \cdot DS + K8 \cdot US \cdot TS + K9 \cdot DS \cdot TS + K10 \cdot E4S \cdot RS^2 + \\ & K11 \cdot RS \cdot US \cdot E4S + K12 \cdot RS \cdot E4S + K13 \cdot US \cdot E4S + K14 \cdot RS^3 + \\ & K15 \cdot E4S^3 + K16 \cdot RS \cdot DS \cdot E4S + K17 \cdot RS \cdot E4S^2 + K18 \cdot US \cdot DS \cdot E4S + \\ & K19 \cdot RS \cdot TS + K20 \cdot E4S \cdot US^2 \end{aligned}$$

### Surface Mode

$$\begin{aligned} FK = & K1 + K2 \cdot US + K3 \cdot TS + K4 \cdot E4S + K5 \cdot RS \cdot US + K6 \cdot RS \cdot TS \\ & + K7 \cdot US \cdot DS + K8 \cdot US \cdot TS + K9 \cdot US \cdot E4S + K10 \cdot RS^2 \\ & + K11 \cdot RS \cdot E4S^2 + K12 \cdot US \cdot RS^2 + K13 \cdot DS \cdot RS^2 + K14 \cdot E4S \cdot RS^2 \\ & + K15 \cdot E4S \cdot US^2 + K16 \cdot E4S \cdot DS^2 + K17 \cdot RS^3 + K18 \cdot RS \cdot US \cdot E4S \\ & + K19 \cdot RS \cdot DS \cdot E4S + K20 \cdot US \cdot DS \cdot E4S \end{aligned}$$

The accuracy of the time-of-flight function is also improved by the addition of a DELT term which is a least-squares function of the initial, atmospheric, and terminal conditions.

### AA Mode

$$\begin{aligned} DELT = & L1 + L2 \cdot E4S \cdot RS^2 + L3 \cdot DS \cdot RS^2 + L4 \cdot US \cdot RS^2 + L5 \cdot RS \cdot E4S^2 \\ & + L6 \cdot RS^3 + L7 \cdot RS \cdot US + L8 \cdot RS \cdot TS \end{aligned}$$

### Surface Mode

$$\begin{aligned} DELT = & L1 \cdot US + L2 \cdot RS \cdot US + L3 \cdot RS \cdot DS + L4 \cdot US \cdot TS \\ & + L5 \cdot DS \cdot TS + L6 \cdot US \cdot RS^2 + L7 \cdot DS \cdot RS^2 + L8 \cdot E4S \cdot RS^2 \\ & + L9 \cdot RS^3 + L10 \cdot RS \cdot US \cdot E4S \end{aligned}$$

In addition to DELT and FK, two other quantities are computed using least-squares expressions. The drift of the projectile due to spin is computed using the following equations:

#### AA Mode

$$\begin{aligned} \text{DRS} = & M1 + M2 \cdot RS \cdot T4S + M3 \cdot RS \cdot E4S + M4 \cdot T4S^2 \\ & + M5 \cdot T4S \cdot E4S + M6 \cdot E4S^2 \end{aligned}$$

$$\text{DRIFT} = \text{DRS} \cdot 10000$$

#### Surface Mode

$$\text{DRS} = M1 \cdot RS + M2 \cdot T4S + M3 \cdot T4S^2$$

$$\text{DRIFT} = \text{DRS} \cdot 10000$$

The fourth quantity computed using a least-squares expression is the ratio of the tangent of the orientation angle of the projectile at termination to the tangent of the superelevation angle. This quantity is computed only in the surface mode and is used to correct for Coriolis effects. The following expression is used to compute this ratio.

$$\begin{aligned} \text{Ratio} = & N1 + N2 \cdot US \cdot RS^2 + N3 \cdot DS \cdot RS^2 + N4 \cdot RS^2 \cdot E4S \\ & + N5 \cdot RS \cdot US \cdot DS \end{aligned}$$

The cross-terms in the above expressions are used to account for the interaction of the independent variables. In particular, the interaction among initial velocity, ballistic density, and slant range to target is large.

The Effective Drag Functions also have several other advantages compared to the MARK 86 ballistic functions.

1. Interpolation as a function of target position angle is not needed in the AA mode since the position angle is one of the independent variables used in the functions.
2. Non-standard values of initial velocity, ballistic density, and ballistic temperature are considered directly in the solution for the superelevation angle and time-of-flight rather than correcting the calculated values of these two quantities for standard conditions.
3. In the surface mode, target height is considered directly in the solution for the superelevation angle through the terms involving the target position angle.
4. The amount of storage needed for the ballistic functions and the related coefficients is much less than the corresponding storage for the MARK 86 functions.
5. Since fewer partitions of the least-squares functions are needed, the amount of computer time used to find the correct partitions is less than for the MARK 86 system.

To compensate for horizontal range wind, the following procedure is used:

1. The horizontal range of the target is modified using the following equations

$$Rh4^* = Rh4 - T4 \cdot Wrh$$

2. The initial velocity of the projectile is modified by the apparent wind velocity.

$$UM = \text{SQRT} \left[ (U \sin Eg)^2 + (U \cos Eg - Wrha)^2 \right]$$

3. After computing a superelevation angle using the equation given previously, the elevation angle is modified using this equation:

$$Eg = \tan^{-1} \frac{UM \cdot \sin Eg^*}{UM \cdot \cos Eg^* + Wrha}$$

The sequence of calculations for both the AA and surface modes and a glossary of terms are given in the appendices.

In addition to the independent variables discussed above, many of the variables which effect the projectile trajectory can be taken into account using closed-form expressions (i.e., no least-squares coefficients are needed). Lateral winds and the affect of own ship motion perpendicular to the line-of-fire on the trajectory can be considered as described in Reference 11. Non-standard projectile weight can be considered by modifying the initial velocity of the projectile and the ballistic density as described in Reference 11.

## V. LEAST-SQUARES PROCEDURES

The expressions previously given for FK, DELT, DRIFT, and RATIO were determined by the BIVOR (Backward Independent Variable Ordering by Regression Sum of Squares) procedure discussed in Reference 12. This procedure ranks least-squares terms according to ascending order of importance. To obtain the expression for FK, a 71-term least-squares fit was carried out using the trajectory data generated by the TRAJ program. The least-squares expression consisted of low powers of each of the six independent variables and products of these powers. By deleting the least important term at each step, the twenty most important terms were selected for inclusion in the final functional form. The same procedure was used to select the final functional forms for DELT, DRIFT, and RATIO. The ranking was carried out using the SELECT computer model coded at NWL. The major difference between SELECT and the model discussed in Reference 12 is that the SELECT program can do least-squares fits and related analyses for several sets of data at one time. This is accomplished by summing the values of the additional regression sum of squares (ARSS) for each term over all the sets of data input to the model. The BIVOR ranking is based on several least-squares fits using the same functional form for each data set. The least-squares coefficients for each data set are given in the appendices.

To attain the functional accuracy needed to adequately approximate the solution to the particle equations of motion, it is necessary to partition the fits as a function of slant range to target. The AA functions required two partitions for both 5"/54 and 3"/50 projectiles. In the surface mode the following number of partitions are used:

5"/54 full charge	3
5"/54 reduced charge	4
3"/50	3

If better accuracy is desired, it is possible to use a larger number of terms for each of the four variables fitted. Terms different from those currently used in the SELECT or RANDOM may be added to the programs with a minimum of new coding.

**FUNCTIONAL ACCURACY

## VI. FUTURE WORK IN BALLISTIC FUNCTIONALIZATION

As discussed previously, NWL and LEC are currently tasked to modify the MARK 86 tactical program to allow the use of the Effective Drag Functions in place of the cubic polynomials currently used. Since the AA portion of the MARK 86 program currently solves for gun orders and fuzing orders for slant ranges exceeding 15,000 yards, the effective drag functions will be extended to include slant ranges greater than the 15,000 yards limit now imposed. It also may be desirable to include more partitions for the surface mode for the 5"/54 full charge projectile. Since new 5-inch ammunition is currently being added to the list of possible ammunition for both the MARK 68 and MARK 86 systems, it will also be necessary to fit the ballistics data for the new rounds.

In addition to these modifications, the joint NWL-LEC study is also aimed at modifying the MARK 86 program to interface with the 8"/55 major caliber lightweight gun (MCLWG). The trajectory data for the 8-inch projectile will be generated in the system by use of the Effective Drag Functions.

It is envisioned that the Effective Drag Functions can be used in future digital fire control systems for projectiles ranging in diameter from 20 millimeters to 16 inches. There are many advantages to having the same functional form in each of the gunfire systems: (1) Only one set of computations is required to generate the least-squares coefficients for each projectile type; (2) If ballistics for a round are changed, new ballistics can be added with a minimum of effort; (3) When analysts work with the coding of each of several systems, it will not be necessary to be familiar with many different types of ballistics functions.

The anticipated addition of guided projectiles to the naval arsenal of projectiles will require ballistic functions that cause the projectile to pass through the acquisition cone and thus acquire the target. The effective drag functions should work extremely well for this purpose since the basic assumptions used in the derivation of the effective drag functions are compatible with the trajectory data for the guided projectile prior to the actuation of guidance.

## APPENDIX A

### DERIVATION OF SUPERELEVATION ANGLE EQUATION

## DERIVATION OF SUPERELEVATION ANGLE EQUATION

The particle equation for horizontal range is:

$$\frac{d\dot{x}}{dt} = \frac{d^2x}{dt^2} = -KV^2 \cos \theta \quad (1)$$

where

$K = \frac{1}{2} \rho \gamma C_D$  is the retardation of the particle  
 $\rho$  is air density  
 $\gamma$  is the reciprocal of the ballistic coefficient  
 $C_D$  is the drag coefficient  
 $V$  is the velocity of the particle  
 $\theta$  is the orientation angle of the particle.

Substituting  $ds/dt$  for  $V$  gives

$$\frac{d\dot{x}}{dt} = -KV \cos \theta \frac{ds}{dt} \quad (2)$$

or

$$d\dot{x} = -KV \cos \theta ds. \quad (3)$$

Substituting  $\dot{x}$  for  $V \cos \theta$  in (3) gives

$$d\dot{x} = -K\dot{x}ds. \quad (4)$$

Separating variables gives:

$$\frac{d\dot{x}}{\dot{x}} = -Kds. \quad (5)$$

Integrating (5) and substituting limits gives

$$\log(V \cos \phi) - \log \dot{x} = Ks \quad (6)$$

where

$\phi$  is the initial value of  $\theta$ .

$$\log(V \cos \phi / \dot{x}) = Ks, \quad (7)$$

$$V \cos \phi / \dot{x} = e^{Ks}, \quad (8)$$

and

$$\dot{x} = V \cos \phi e^{-Ks} = \dot{x}_0 e^{-Ks}. \quad (9)$$

Also

$$\frac{V^2}{r} = g \cos \theta \quad (10)$$

where

$r$  is the radius of curvature, and  
 $g$  is the acceleration due to gravity.

Since  $V = \dot{x} \sec \theta$  and  $r = \frac{-ds}{d\theta}$ , equation (10) becomes:

$$\frac{\dot{x}^2 \sec^2 \theta}{-ds/d\theta} = g \cos \theta \quad (11)$$

or

$$\dot{x}^2 \sec^2 \theta = (-g \cos \theta) \frac{ds}{d\theta}. \quad (12)$$

Therefore

$$\sec^2 \theta d\theta = \frac{-g \cos \theta ds}{\dot{x}^2} \quad (13)$$

Substituting  $dx$  for  $ds \cos \theta$  gives:

$$\sec^2 \theta d\theta = \frac{-g dx}{\dot{x}^2} \quad (14)$$

Substituting the expression from (9) into Equation (14) gives:

$$\sec^2 \theta d\theta = \frac{-g dx}{V^2 \cos^2 \phi e^{-2Ks}} \quad (15)$$

or

$$\sec^2 \theta d\theta = \frac{-ge^{2Ks} dx}{V^2 \cos^2 \phi} \quad (16)$$

Using the approximation  $s = x$  in (16) gives.

$$\sec^2 \theta d\theta = \frac{-ge^{2Kx} dx}{V^2 \cos^2 \phi} \quad (17)$$

Integrating (17) between appropriate limits gives:

$$\tan \theta - \tan \phi = \left[ \frac{-g}{2KV^2 \cos^2 \phi} \right] \left[ e^{2Kx} - 1 \right] \quad (18)$$

Let

$$e^{2Kx} = 1 + 2Kx + \frac{(2Kx)^2}{2} + \frac{(2Kx)^3}{6}$$

$$e^{2Kx} = 1 + 2Kx + 2K^2x^2 + \frac{4}{3}K^3x^3$$

$$e^{2Kx} - 1 = 2Kx + 2K^2x^2 + \frac{4}{3}K^3x^3$$

or

$$e^{2Kx} - 1 = 2Kx \left[ 1 + Kx + \frac{2}{3} K^2 x^2 \right] \quad (19)$$

Substituting this expression into (18) gives:

$$\frac{dy}{dx} = \tan \theta = \tan \phi - \left[ \frac{g}{2KV^2 \cos^2 \phi} \right] \left[ 2Kx(1 + Kx + \frac{2}{3} K^2 x^2) \right] \quad (20)$$

or

$$dy = \left[ \tan \phi - \frac{gx}{V^2 \cos^2 \phi} (1 + Kx + \frac{2}{3} K^2 x^2) \right] dx. \quad (21)$$

Integrating (21) gives:

$$y = x \tan \phi - \left[ \frac{gx^2}{2V^2 \cos^2 \phi} \right] \left[ 1 + \frac{2Kx}{3} + \frac{K^2 x^2}{3} \right]. \quad (22)$$

Let  $N = 1 + \frac{2Kx}{3} + \frac{K^2 x^2}{3}$ :

$$y = x \tan \phi - \frac{Ngx^2}{2V^2 \cos^2 \phi}. \quad (23)$$

Let  $y = 0$ :

$$x \tan \phi = \frac{Ngx^2}{2V^2 \cos^2 \phi} \quad (24)$$

$$(2V^2 \cos^2 \phi)(x \tan \phi) = Ngx^2$$

$$2V^2 \cos^2 \phi \tan \phi = Ngx \quad (25)$$

$$2V^2 \cos \phi \sin \phi = Ngx \quad (26)$$

$$\sin 2\phi = \frac{Ngx}{V^2} . \quad (27)$$

Therefore

$$\phi = \left[ \sin^{-1} \left( \frac{Ngx}{V^2} \right) \right] / 2 \quad (28)$$

where

$$N = 1 + \frac{2Kx}{3} + \frac{K^2 x^2}{3} .$$

**APPENDIX C**

**GLOSSARY OF TERMS**

## GLOSSARY OF TERMS

A	Intermediate quantity used in computation of T4
AG	Intermediate Coriolis coefficient
AZ	Azimuth of the line of fire (measured clockwise from the north)
BG	Intermediate Coriolis coefficient
DELT	Intermediate quantity used in computation of T4
DELX	Change in range corresponding to an increase of ten minutes in Eg (Yards)
DELXO	Change in range due to Coriolis effect (Feet)
DG	Intermediate Coriolis coefficient
DOMEGA	Cross range due to Coriolis effect (Feet)
DRIFT	Drift (Feet)
DRS	Drift $\times 10^{-4}$ (Feet)
DS	Ballistic density $\times 10^{-2}$ (Percent of Standard)
D1	Coefficient in DELX expression
Eg	Elevation angle with respect to ground (Degrees)
Eg*	Elevation angle with respect to air (Degrees)
E4*	Aiming position angle (Degrees)
E4S	Aiming position angle (Radians)
FK	Intermediate quantity used in computation of Eg
G	Gravity constant (32.174 Ft/Sec <sup>2</sup> )
K1 - K20	Coefficients for FK expression
L	Latitude
L1 - L10	Coefficients for DELT expression

M1 – M5	Coefficients for DRS expression
N	Intermediate quantity used in computation of Eg
N1 – N5	Coefficients for ratio expression
Ratio	Intermediate expression used in computing Coriolis effects
Rh4	Horizontal range to aim point (Feet)
Rh4*	Horizontal range to aim point modified by wind effect (Feet)
RS	Slant range to aim point modified by wind effect $\times 10^{-4}$ (Feet)
Rv	Vertical range to aim point (Feet)
R4	Slant range to aim point (Feet)
R4*	Slant range to aim point modified by wind effect (Feet)
sin2	Sine of twice the superelevation angle
TANW	Tangent of angle to fall
TS	Ballistic temperature $\times 10^{-2}$ (Degrees Fahrenheit)
T4	Projectile time-of-flight to aim point (Sec)
T4S	Projectile time-of-flight to aim point $\times 10^{-2}$ (Sec)
U	Initial velocity of projectile with respect to ground (Ft/Sec)
Um	Initial velocity of projectile with respect to air (Ft/Sec)
US	Initial velocity of projectile with respect to air $\times 10^{-4}$ (Ft/Sec)
V4*	Superelevation angle (Degrees)
Wrh	True horizontal ballistic wind (Ft/Sec)
Wrha	Apparent horizontal ballistic wind (Ft/Sec)
Ws	True horizontal ballistic wind $\times 10^{-2}$ (Knots)

**COMPUTER LISTING FOR "SELECT" PROGRAM**

SELECT

PROGRAM

PROGRAM SELECT(INPUT, OUTPUT, TAPE2, TAPE3)

\*\*\*\* SELECT \*\*\*\*

THIS PROGRAM SELECTS THE TERMS WHICH ARE MOST NEEDED STATISTICALLY TO FIT A SET OF DATA IN THE LEAST SQUARES SENSE. THE MODEL USES THE RIVOR (BACKWARD INDEPENDENT VARIABLE ORDERING BY REGRESSION SUM OF SQUARES) PROCESS DESCRIBED IN NWL TECHNICAL REPORT NO. 2435.

THIS PROGRAM DIFFERS FROM THE DA-URCA PROGRAM DESCRIBED IN TR-2035 IN THAT THE RIVOR PROCESS IS USED FOR MORE THAN ONE SET OF DATA AT A TIME. THIS IS ACCOMPLISHED BY SUMMING THE VALUES OF THE ADDITIONAL REGRESSION SUM OF SQUARES (ARSS) CORRESPONDING TO EACH TERM OVER ALL THE SETS OF DATA INPUT TO THE MODEL.

THE MODEL FIRST DOES A LEAST-SQUARES FIT USING THE TERMS DESCRIBED TO THE MODEL BY CARD TYPE 3. AT THAT TIME THE FIT IS DONE, THE MODEL COMPUTES THE ARSS FOR EACH TERM AND DETERMINES THE TERM WITH MINIMUM VALUE OF ARSS. A NEW FIT IS THEN DONE WITH THAT TERM DELETED. THIS PROCESS IS REPEATED UNTIL THE NUMBER OF TERMS REMAINING EQUALS IKEEP (INPUT ON CARD TYPE 1)

THE FORMAT FOR CARD TYPE 5 DESCRIBING INPUT DATA POINTS IS IDENTICAL TO THE FORMAT FOR THE CARDS PUNCHED BY THE TRAJ PROGRAM. THESE CARDS CAN BE USED DIRECTLY OR CARDS CAN BE PUNCHED BY HAND TO USE AS DATA POINTS FOR THE MODEL. (FOR A PARTICULAR TYPE OF FIT, NOT ALL VARIABLES ARE READ INTO MEMORY.)

FIVE DIFFERENT TYPES OF FITS CAN BE COMPUTED DEPENDING ON THE VALUE OF ITYPE---SEE INPUT GUIDE FOR DETAILS.

TO DETERMINE WHICH TERMS ARE AVAILABLE FOR USE IN THE FIT FUNCTION, SET THE SECTION OF CODING ENTITLED \*\*\*\* DEFINE TERMS FOR FIT AND EVALUATION \*\*\*\*. ADDITIONAL TERMS CAN BE ADDED TO THE MODEL BY A SIMPLE CHANGE IN THE CODING.

TWO TEMPORARY DISK FILES (TAPE2 AND TAPE3) ARE USED TO STORE THE ELEMENTS OF THE NORMAL MATRIX AT EACH STEP IN THE RIVOR PROCESS. THIS SIMPLIFIES THE CONSTRUCTION OF THE NORMAL MATRIX AT THE NEXT STEP IN RIVOR.

IF A \*DELT\* FIT (ITYPE = 2) IS DONE, THE MODEL WILL COMPUTE THE VALUE OF DELT TO BE USED IN THE FIT FROM THE DATA ON CARD TYPE 5.

IF A \*DRIFT\* FIT (ITYPE= 3) IS DONE, TIME OF FLIGHT IS USED AS AN INDEPENDENT VARIABLE INSTEAD OF BALLISTIC RANGE WIND.

IF INT = 1, THE \*ELANG\*, \*REGDLY\*, AND \*ANFAL\* ARRAYS ARE NOT USED.---THUS, A FIT CAN BE DONE FOR PROJECTILES OTHER THAN THOSE COVERED BY THE ID CONTROL BY NOT USING WEIGHTS IN CONSTRUCTING THE NORMAL MATRIX. IN THIS CASE, SET ID TO SOME VALUE LESS THAN TEN.

ODC 5633 FTN V5.0-PS33\* OPT=1 J7/26/72 16.54.52.

12. SPONSORING MILITARY ACTIVITY

13. ABSTRACT

The Effective Drag Functions derived by the Naval Weapons Laboratory for the computation of gun ballistic data in digital gunfire control systems are presented. The accuracy and derivation of the functions are given as well as the least-squares coefficients computed for 3- and 5-inch projectiles. FORTRAN listings of the three programs used in the computation of the coefficients are given in the appendices.
